Listen claude, you messed up a lot, in browser you made game look visually much better, did I not tell you to make it like INSIDE

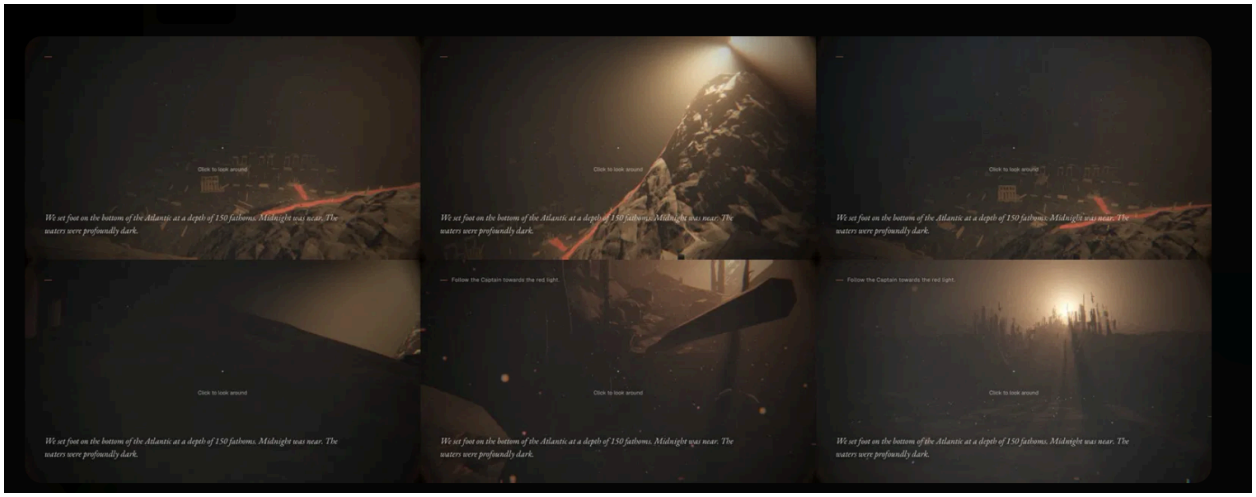

See this image, look at how underwater light looks like, you made it like subnautica, you got the ambiance of the “Lost Continent right“ but really messed

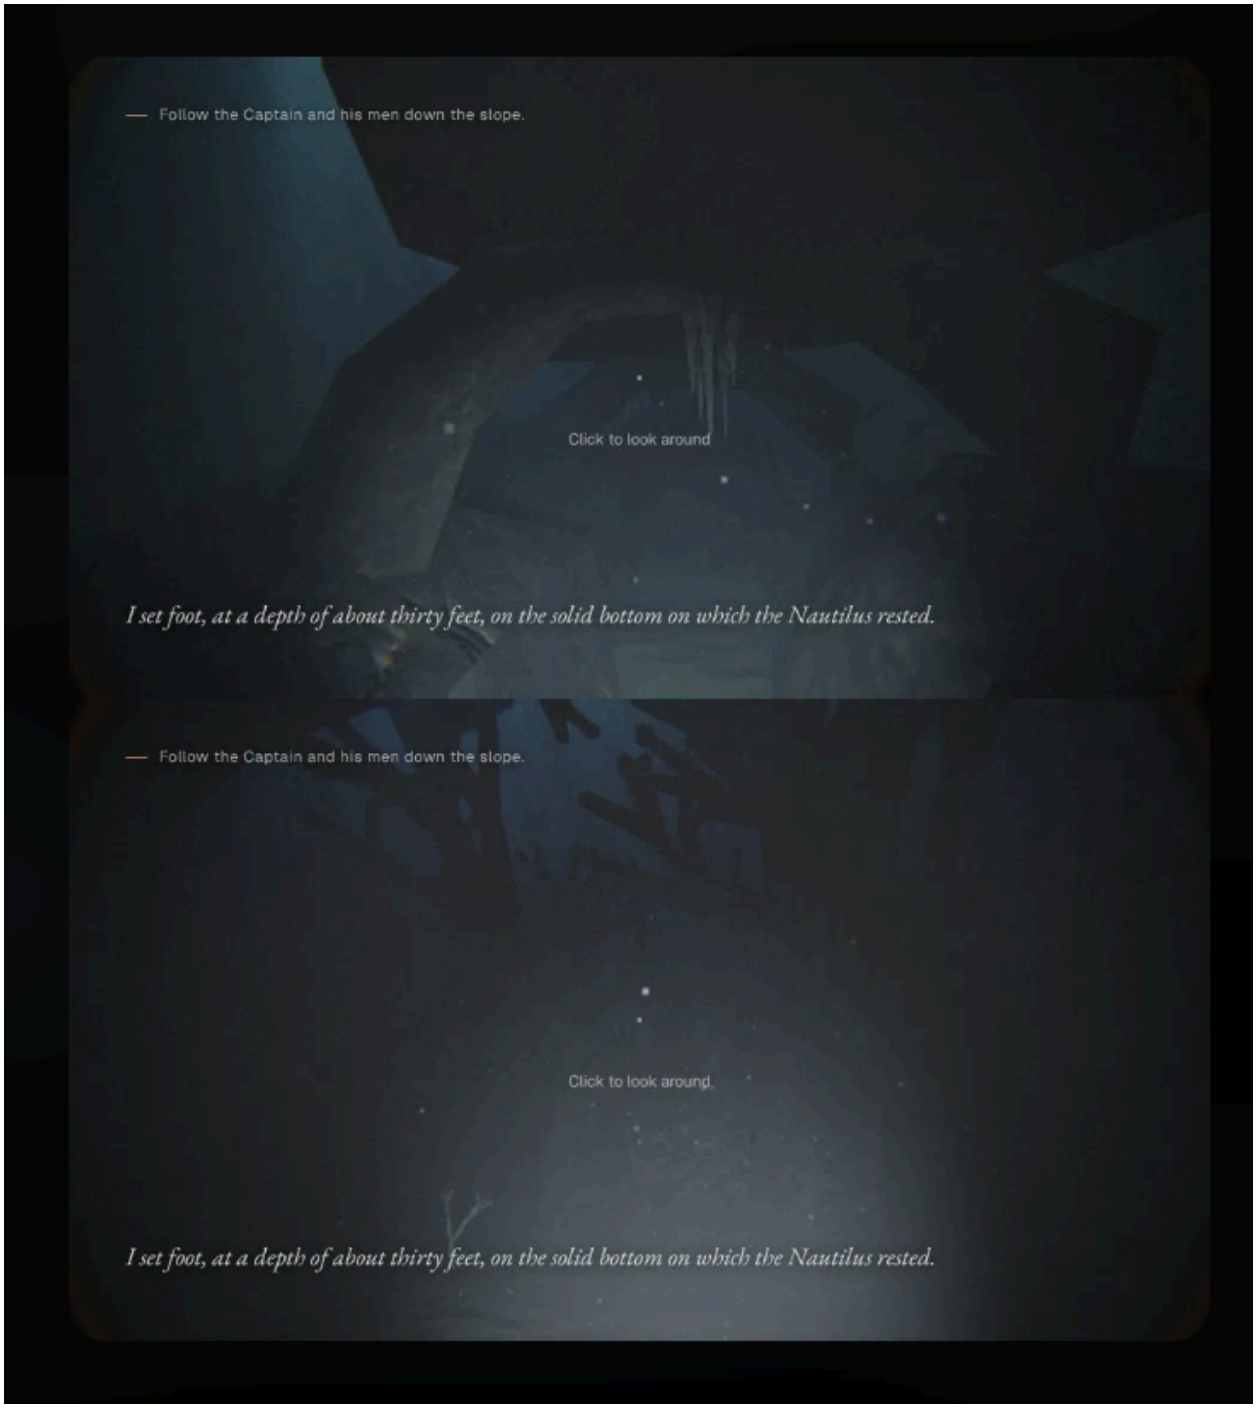

up the Unity version.

— Follow the Captain and his men down the slope.
Click to look around
I set foot, at a depth of about thirty feet, on the solid bottom on which the Nautilus rested.

I set foot, at a depth of about thirty feet, on the solid bottom on which the Nautilus rested.

Take a look at these images, there are so many bugs, fishes are glitching through the submarine, and the doors and rooms look nothing like how Jules Verne describes it, like you have completely gone away from the original story, the details are terrible, like its like roblox, where are the intense tiny details, in the browser one you sent, you could see what individual painting used to tell, now you can't and the submarine interior looks like cubes stuck together.

The water physics and lighting looks bad too, its nothing like Inside, and the flora and fauna at sea bed looks as if a kid drew something, the Lost continent was a nightmare to look at, the lighting looks so bad and what are those trees, like they look like land trees.

Look at this The Lighting of INSIDE

by Marek Bogdan, 2016

As you might have heard, INSIDE was made using a pretty heavily-modified Unity engine. One of the most intensely worked on areas was rendering, and I think that looking at the game, this is quite obvious.

What might not be so obvious is that, rather than using an 'automated' lighting solution, our team opted for a set of tools that relied on manual placement of the various effects that simulate realistic lighting, including: bounced light, specular light, rim light, AO and even the good old cast shadow decals.

In other words: the lighting you see in INSIDE is all about layers of hand-placed decals – there is no global illumination or even automated AO at play here.

One reason for this was that the style required a painterly look that felt as close as possible to Morten's concepts. Another was that modeling (and lighting) detail had to be controlled very precisely depending on distance from the camera and gameplay or narrative focus. Of course, this being a side-scroller had a lot to do with the decision as well – knowing precisely where the camera was at any given time allowed us to tweak the effects with as much precision and subtlety as we liked.

Here are some examples of this 'targeted high fidelity lighting' in scenes I worked on:

A little corridor leading up to the Cargo Hall area. Bounce light, subtle specular on the pipes and ambient occlusion effects are all accomplished using hand-placed decals. In scenes like this, I believe that being very diligent about having every available effect support the

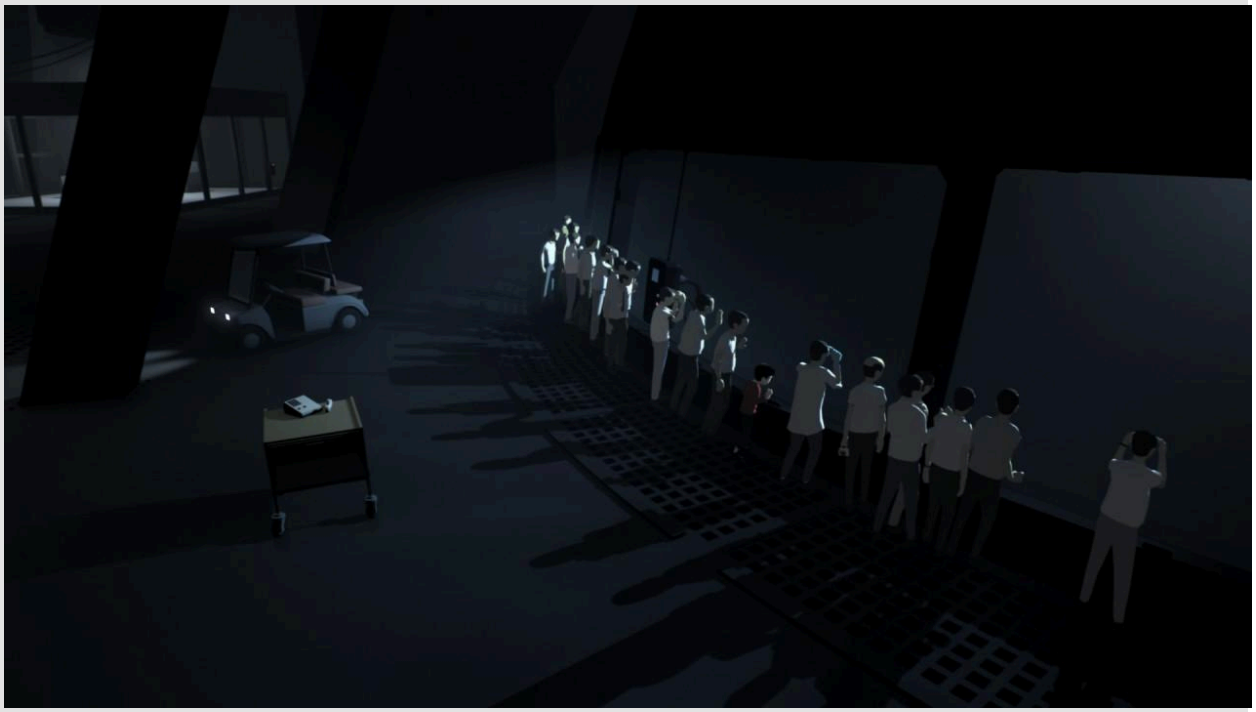

lighting setup is very important. Note for example how the cube map reflection on the glass energy meter (round cylinder on the upper right) is accurately simulating where the bright area is. Extremely subtle but again: these things add up and they do matter.

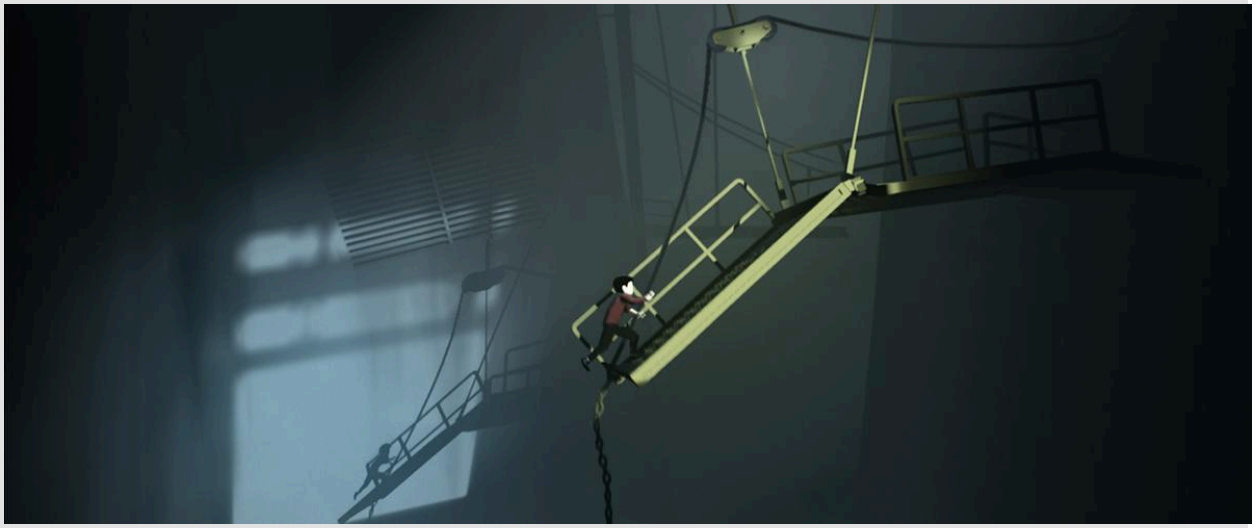

Another extremely simple room that owes everything to detailed lighting.

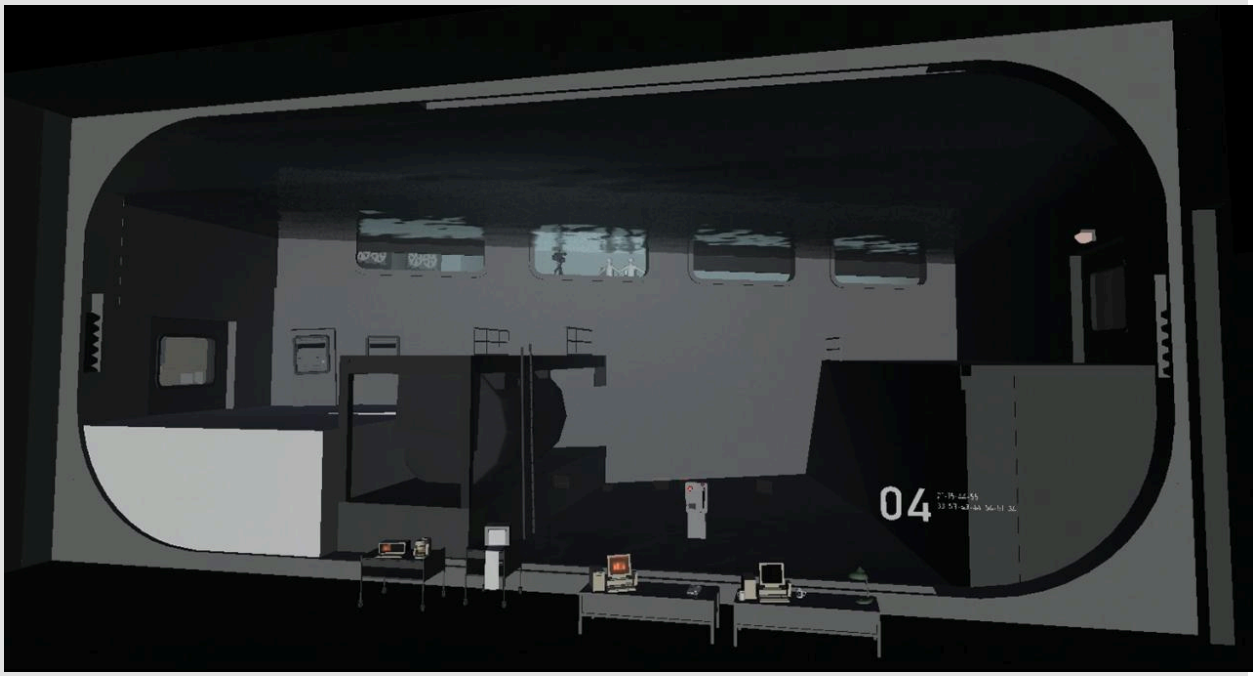

Later in the project, we began using cookies more and more. Doing so added some texture to our very simple scenes and sometimes helped us create the illusion of using more sophisticated shadowing techniques.

One of the interesting technical details of the torch effect is that the shadows emanating from the Boy's feet are actually just simple shadow decals that track the position of the torch and rotate accordingly around the Boy's feet. They even scale up and down depending on how high the torch is off the ground. We couldn't use standard shadows here because casting from a point light would have been much too expensive.

04

Above you can see how a room looks (in Unity) before/after it is lit and vfx are added.
I should say that as an artist, I loved setting up lighting using this solution. Props to MikkelG, MikkelS and Tobias for their skill and boundless enthusiasm in providing us with the tools and ideas behind it.

Learn something from it damn it, lock in dude.

The door ways get blocked by some models and the panels and light levers are out of place, in the browser you had proper animation and fade in light and fade out, because its incandescent not freaking LED.

You are not at all referring to the book and what was that engine room dude, the RPM or crank and gear were so off, and like you are not even trying at this point, everything is too smooth, when you are looking at the painting make it so that we can see painting next to our message when you see its details so we can see the painting better, same with artifacts, you literally gave up on all details and messed everything up.

REFER TO THE DAMN BOOK FOR EVERY DAMN MODEL AND DETAIL, it should be as if you are playing the book, not an adaptation, we are paying you 2000 bucks not to give such crap where you don't even try.

Redesign everything, every detail, kitchen, bathroom and everything should be 1:1 to the book.

Animations need to get better, they look crap, work on it, feet are reversed and more.

Optimise the game and make the visuals more cinematic and get the details on point this time.

It should be the book as the game not a fan parody, think of yourself the best videogame artist and an one man army and in light if Jules Verne.
